2.1. Running AtlasMap Data Mapper UI standalone	5
2.2. Running AtlasMap data mapping with Apache Camel	5
3. Import Files in UI	6
3.1. Import XML/JSON schema or instance or Java class files	6
4. Design Mappings in UI	21
4.1. Find the data field that you want to map	21
4.2. Map one source field to one target field	21
4.3. Example of missing or unwanted data when combining or separating fields	22
4.4. Combine multiple source fields into one target field	23
4.5. Separate one source field into multiple target fields	25
4.6. Transform source or target data	26
4.7. Applying conditions to mappings	35
4.8. View the mappings	39
4.9. Descriptions of available transformations	39
5. Export Files in UI	47
5.1. Export AtlasMap Data Mapper Catalog File	47
6. Reset Files in UI	49
6.1. Reset the AtlasMap Data Mapper	49

AtlasMap is a data mapping solution with an interactive web based user interface. It simplifies configuration of an integration that handles different types of data represented by XML schema or instance files, JSON schema or instance files or Java class files. You design your data mapping and transformations in the AtlasMap Data Mapper UI canvas, and then execute that mapping by means of the AtlasMap runtime engine. We provide standard transformations or we support custom, user-defined transformations. We also have a camel-atlasmap component which consumes an AtlasMap mapping definition which can process data mappings as a part of a Camel route.

# Chapter 1. How to define an AtlasMap data mapping?

AtlasMap focuses more on field-by-field mapping than whole document transformation. It allows users to choose individual fields from incoming documents, and map them to fields of the outgoing document [1: It doesn't mean we won't address whole document mapping at all. For example we have a plan to support bulk mapping by detecting the same object structure at both sides of documents (#86).]. So then, what is **field** in AtlasMap? Let's see an example with XML:

```
<order>
  <orderId value="0123">
  <items>
    <item>
      <itemId>Orange</itemId>
      <quantity value="1"/>
    </item>
    <item>
      <itemId>Apple</itemId>
      <quantity value="2"/>
    </item>
  </items>
</order>
```

In this XML instance document, `/order/items/item[0]/itemId` and `/order/orderId/@value` are terminal fields. In AtlasMap, only terminal fields can be selected to be added into a mapping. Other parent elements like `/order`, `/order/orderId`, `/order/items/item[0]` are not selectable. Instead it can be expanded to see descendant fields.

## 1.1. Field Types

There are roughly 3 types of fields that differentiate behavior.

### 1.1.1. Terminal field

Terminal field is selectable in AtlasMap Data Mapper UI and can participate in mapping directly. Its path identifies the value in the document payload.

### 1.1.2. Parent field

Also called as Complex field. Parent field cannot participate in mapping directly, but it's expandable in UI so user can see descendant fields.

### 1.1.3. Collection field

Collection field is a kind of terminal field. It's selectable and mappable. The difference is that either the collection field itself or any of its parent fields is a collection. In an example XML above, `item` is

a collection which could be multiple. Therefore `/order/items/item[]/itemId` is a collection field. In a programming term, it's just array, List, etc. One thing to keep in mind is that, "how many items are going to be delivered?" is not decided at design time. Each transaction should be able to deliver a different number of items with same mapping definition.

## 1.2. Mapping Types

Looking from field multiplicity aspects, there are 4 types of mapping in AtlasMap.

### 1.2.1. One to One

Map from one source field to one target field.

### 1.2.2. Many to One

Map from multiple source fields to one target field. Many-to-One mapping requires one Many-to-One transformation to map multiple values into one. At this moment, we only support combining values with a delimiter. Other Many-to-One transformation will be added once (#912) is fixed.

### 1.2.3. One to Many

Map from one source field to multiple target fields. One-to-Many mapping requires one One-to-Many transformation to map one value into multiple values. At this moment, we only support separating a value with a delimiter. Other One-to-Many transformation will be added once (#912) is fixed.

### 1.2.4. For Each

Map from one source collection field to one target collection field. It iterates One-to-One mapping for each element in the collection field.

## 1.3. Transformation

In addition to simply mapping the source field value to target field value, AtlasMap supports transformations that apply to both source and/or target field in the mapping. Transformation is a single function to be applied to a field value, such as `Uppercase` which changes all characters of the string field value to uppercase. You can add any number of transformations to the mapped field from `Mapping Detail` pane at right side in the UI.

Allowing transformations to be added for both source and target field might not immediately make sense. But let's think about Many-to-One case, to combine `Street`, `City`, `State` into comma separated single string. If you want to uppercase only `State`, then you need to add on `State` source field. If you want to uppercase everything, then it's easier to add just one `Uppercase` transformation on the target field as opposed to add it for each source fields. In other words we can call source field transformation as Pre-mapping, and the target field transformation as Post-mapping.

Multiplicity transformations described above are special type of transformations which changes multiplicity. Multiplicity transformations can be added only when it's One-to-Many or Many-to-One

mapping.

# Chapter 2. Quickstart

## 2.1. Running AtlasMap Data Mapper UI standalone

Here is the shortest path to run standalone AtlasMap.

1. Download the AtlasMap standalone jar

```
wget http://central.maven.org/maven2/io/atlasmap/atlasmap-standalone/${VERSION}/atlasmap-standalone-${VERSION}.jar
```

2. Run AtlasMap standalone

```
$ java [ -Datlasmap.adm.path=/path/to/example.adm ] -jar atlasmap-standalone-${VERSION}.jar
```

Now AtlasMap Data Mapper UI is available at <http://127.0.0.1:8585/> The .adm file can be created with the export icon on the main toolbar.

## 2.2. Running AtlasMap data mapping with Apache Camel

TODO

camel-atlasmap endpoint use IN body as a default source document of mappings. If IN body is a `java.util.Map`, key is used as a Document ID and corresponding value is used as a Document payload.

```
...
from("direct:start")
  .to("atlas:atlas-mapping.adm")
  .log("${body}")
...
```

# Chapter 3. Import Files in UI

## 3.1. Import XML/JSON schema or instance or Java class files

Data mapping fundamentally involves morphing one data shape into another. A user defines these shapes using XML schemas, JSON notation or by establishing a simple Java class. The following sections examine each file type independently.

- JSON Schema File: **JSONSchema.json**

```
{
  "$schema": "http://json-schema.org/schema#",
  "description": "Order",
  "type": "object",
  "properties": {
    "order": {
      "type": "object",
      "properties": {
        "address": {
          "type": "object",
          "properties": {
            "street": { "type": "string" },
            "city": { "type": "string" },
            "state": { "type": "string" },
            "zip": { "type": "string" }
          }
        },
        "contact": {
          "type": "object",
          "properties": {
            "firstName": { "type": "string" },
            "lastName": { "type": "string" },
            "phone": { "type": "string" }
          }
        },
        "orderId": { "type": "string" }
      }
    },
    "primitives": {
      "type": "object",
      "properties": {
        "stringPrimitive": { "type": "string" },
        "booleanPrimitive": { "type": "boolean" },
        "numberPrimitive": { "type": "number" }
      }
    },
    "primitiveArrays": {
```

```

    "type": "object",
    "properties": {
      "stringArray": {
        "type": "array",
        "items": { "type": "string" }
      },
      "booleanArray": {
        "type": "array",
        "items": { "type": "boolean" }
      },
      "numberArray": {
        "type": "array",
        "items": { "type": "number" }
      }
    }
  },
  "addressList": {
    "type": "array",
    "items": {
      "type": "object",
      "properties": {
        "street": { "type": "string" },
        "city": { "type": "string" },
        "state": { "type": "string" },
        "zip": { "type": "string" }
      }
    }
  }
}

```

To import this file into the AtlasMap Source panel, select the import icon at the top of the panel.

An **Open File** dialog appears. Select the location for the JSONSchema.json file.

The fields now appear in the Source panel as you defined them in the imported JSON schema.

Now consider the import an XML schema into the Target panel.

- XML Schema File: **XMLSchema.xml**

```
<d:SchemaSet xmlns:d="http://atlasmap.io/xml/schemaset/v2"
xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <xsd:schema targetNamespace="http://syndesis.io/v1/swagger-connector-
template/request" elementFormDefault="qualified">
    <xsd:element name="request">
      <xsd:complexType>
        <xsd:sequence>
          <xsd:element name="body">
            <xsd:complexType>
              <xsd:sequence>
                <xsd:element ref="Pet" />
              </xsd:sequence>
            </xsd:complexType>
          </xsd:element>
        </xsd:sequence>
      </xsd:complexType>
    </xsd:element>
  </xsd:schema>
</d:SchemaSet>
```

```

    </xsd:element>
</xsd:schema>
<d:AdditionalSchemas>
  <xsd:schema>
    <xsd:element name="Pet">
      <xsd:complexType>
        <xsd:sequence>
          <xsd:element name="id" type="xsd:decimal" />
          <xsd:element name="Category">
            <xsd:complexType>
              <xsd:sequence>
                <xsd:element name="id" type="xsd:decimal" />
                <xsd:element name="name" type="xsd:string" />
              </xsd:sequence>
            </xsd:complexType>
          </xsd:element>
          <xsd:element name="name" type="xsd:string" />
          <xsd:element name="photoUrl">
            <xsd:complexType>
              <xsd:sequence>
                <xsd:element name="photoUrl" type="xsd:string"
maxOccurs="unbounded" minOccurs="0" />
              </xsd:sequence>
            </xsd:complexType>
          </xsd:element>
          <xsd:element name="tag">
            <xsd:complexType>
              <xsd:sequence>
                <xsd:element name="Tag" maxOccurs="unbounded" minOccurs="0">
                  <xsd:complexType>
                    <xsd:sequence>
                      <xsd:element name="id" type="xsd:decimal" />
                      <xsd:element name="name" type="xsd:string" />
                    </xsd:sequence>
                  </xsd:complexType>
                </xsd:element>
              </xsd:sequence>
            </xsd:complexType>
          </xsd:element>
          <xsd:element name="status" type="xsd:string" />
        </xsd:sequence>
      </xsd:complexType>
    </xsd:element>
  </xsd:schema>
</d:AdditionalSchemas>
</d:SchemaSet>

```

In the data mapper, click the import icon at the top of the Target panel.

An **Open File** dialog appears. Navigate to the XMLSchema.xml file and select it. The fields now appear in the Target panel as you defined them in the imported XML schema. The fields are expanded to show more detail.

You import instance files in the same way. Instance files define a separate namespace, which also defines a few special attributes. For example:

- JSON Schema Instance File: **JSONSchemaInst.json**

```

{
  "order": {
    "address": {
      "street": "123 any st",
      "city": "Austin",
      "state": "TX",
      "zip": "78626"
    },
    "contact": {
      "firstName": "james",
      "lastName": "smith",
      "phone": "512-123-1234"
    },
    "orderId": "123"
  },
  "primitives": {
    "stringPrimitive": "some value",
    "booleanPrimitive": true,
    "numberPrimitive": 24
  },
  "addressList": [
    { "street": "123 any st", "city": "Austin", "state": "TX", "zip": "78626"
  },
    { "street": "123 any st", "city": "Austin", "state": "TX", "zip": "78626"
  },
    { "street": "123 any st", "city": "Austin", "state": "TX", "zip": "78626"
  },
    { "street": "123 any st", "city": "Austin", "state": "TX", "zip": "78626"
  }
  ]
}

```

- XML Schema Instance File: **XMLSchemaInst.xml**

```

<ns:Xml0E xmlns:ns="http://atlasmap.io/xml/test/v2"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://atlasmap.io/xml/test/v2 atlas-xml-test-model-v2.xsd ">
  <ns:orderId>ns:orderId</ns:orderId>
  <ns:Address>
    <ns:addressLine1>ns:addressLine1</ns:addressLine1>
    <ns:addressLine2>ns:addressLine2</ns:addressLine2>
    <ns:city>ns:city</ns:city>
    <ns:state>ns:state</ns:state>
    <ns:zipCode>ns:zipCode</ns:zipCode>
  </ns:Address>
  <ns:Contact>
    <ns:firstName>ns:firstName</ns:firstName>
    <ns:lastName>ns:lastName</ns:lastName>
    <ns:phoneNumber>ns:phoneNumber</ns:phoneNumber>
    <ns:zipCode>ns:zipCode</ns:zipCode>
  </ns:Contact>
</ns:Xml0E>

```

Using the same procedure as before, import instance files into either the Source or Target panel.

There does exist one other method for establishing mappable fields within the AtlasMap data mapper. A Java class can be established where each field is represented as a class-wide public entity. Arrays and data types are more discretely defined. For example:

- Java File: **Bicycle.java**

```

package io.paul;
import io.paul.GeoLocation;

public class Bicycle {
  public int cadence;
  public int gear;
  public int speed;
  public float[] seatHeight;
  public String[] color;
  public GeoLocation geoLocation;
}

```

- Java File: **GeoLocation.java**

```

package io.paul;

public class GeoLocation {
  double lattitude;
  double longitude;
}

```

Compile the Java files and assemble the results into a Java archive file, for example, **Bicycle.jar** in the following lines:

```
javac -cp io.paul:. -d . GeoLocation.java Bicycle.java
jar cvf ../Bicycle.jar *
```

Now you can import the **Bicycle.jar** archive into AtlasMap. The import procedure is slightly different for Java class archives. You must:

Import the file into AtlasMap. Select the import icon **on the main tool bar**, not on the panel.

An **Open File** dialog appears. Navigate to the **Bicycle.jar** file and select it.

Select the plus icon (+) on the Source or Target panel.

A dialog appears "Establish your class in the Sources panel." In the **Class package name:** input field, enter the class package name of the Java class you have defined. In the *Bicycle.jar* example, the class package name is *io.paul.Bicycle*.

You will now see the fields you created in your Java class file appear in the selected panel.

AtlasMap Data Mapper UI

Source

- > Properties
- > Constants
- JSONSchema
- > addressList
- > order
- > primitiveArrays
- > primitives
- Io.paul.Bicycle
  - cadence
  - color
  - gear
  - > geoLocation
  - seatHeight
  - speed

32 fields

Target

- XMLSchema
  - tns:request
    - tns:body
      - Pet
        - Category
          - id
          - name
        - id
        - name
        - photoUrl
          - status
        - tag
          - Tag
            - id
            - name

15 fields

You have now defined the source and target data shapes.

# Chapter 4. Design Mappings in UI

## 4.1. Find the data field that you want to map

In a relatively simple integration, mapping data fields is easy and intuitive. In more complex integrations or in integrations that handle large sets of data fields, mapping from source to target is easier when you have some background about how to use the data mapper.

The data mapper displays two columns of data fields:

- **Sources** is a list of the data fields that you can map to target fields.
- **Target** is a list of the data fields that you can map source fields to.

To quickly find the data field that you want to map, you can do any of the following:

- Search for it.

The **Sources** panel and the **Target** panel each have a search field at the top. If the search field is not visible, click  at the top right of the **Sources** or **Target** panel.

- Enter the names of the fields that you want to map.

To do this, in the upper right of the **Configure Mapper** page, click the plus sign to display the **Mapping Details** panel. In the **Sources** section, enter the name of the source field. In the **Action** section, accept the default **Map**, which maps one field to one other field. Or, select **Combine** or **Separate**. In the **Target** section, enter the name of the field that you want to map to.

- Expand and collapse folders to limit the visible fields.

## 4.2. Map one source field to one target field

The default mapping behavior maps one source field to one target field. For example, map the **Name** field to the **CustomerName** field.

### *Procedure*

1. In the **Sources** panel, click the data field that you want to map from.

You might need to expand a folder to see the data fields that it provides.

When there are many source fields, you can search for the field of interest by clicking the  and entering the name of the data field in the search field.

2. In the **Target** panel, click the data field that you want to map to.

The data mapper displays a line that connects the two fields that you just selected.

3. Optionally, preview the data mapping result. This is useful when you add a transformation to the mapping or when the mapping requires a type conversion.

- a. In the upper right of the data mapper, click  and select **Show Mapping Preview** to

display a text input field on the source field and a read-only result field on the target field.

- b. In the source field's data input field, enter text. Click somewhere outside this text box to display the mapping result in the read-only field on the target field.
  - c. Optionally, to see the result of a transformation, add a transformation in the **Mapping Details** panel.
  - d. Hide the preview fields by clicking [Editor settings] again and selecting **Show Mapping Preview**.
4. Optionally, to confirm that the mapping is defined, in the upper right, click  to display the defined mappings.

You can also preview data mapping results in this view. If preview fields are not visible, click  and select **Show Mapping Preview**. Enter data as described in the previous step. In the table of defined mappings, preview fields appear for only the selected mapping. To see preview fields for another mapping, select it.

Click  again to display the data field panels.

5. In the upper right, click **Done** to save the mapping.

#### Alternative procedure

Here is another way to map a single source field to a single target field:

1. In the **Configure Mapper** page, in the upper right, click the plus sign to display the **Mapping Details** panel.
2. In the **Sources** section, enter the name of the source field.
3. In the **Action** section, accept the default **Map** action.
4. In the **Target** section, enter the name of the field that you want to map to and click **Enter**.

## 4.3. Example of missing or unwanted data when combining or separating fields

In a data mapping, you might need to identify missing or unwanted data when a source or target field contains compound data. For example, consider a **long\_address** field that has this format:

*number street apartment city state zip zip+4 country*

Suppose that you want to separate the **long\_address** field into discrete fields for **number**, **street**, **city**, **state**, and **zip**. To do this, you select **long\_address** as the source field and then select the target fields. You then add padding fields at the locations for the parts of the source field that you do not want. In this example, the unwanted parts are *apartment*, *zip+4*, and *country*.

To identify the unwanted parts, you need to know the order of the parts. The order indicates an index for each part of the content in the compound field. For example, the **long\_address** field has 8 ordered parts. Starting at 1, the index of each part is:

1	<i>number</i>
---	---------------

2	<i>street</i>
3	<i>apartment</i>
4	<i>city</i>
5	<i>state</i>
6	<i>zip</i>
7	<i>zip+4</i>
8	<i>country</i>

In the data mapper, to identify *apartment*, *zip+4*, and *country* as missing, you add padding fields at indexes 3, 7, and 8. See [Separate one source field into multiple target fields](#).

Now suppose that you want to combine source fields for **number**, **street**, **city**, **state**, and **zip** into a **long\_address** target field. Further suppose that there are no source fields to provide content for *apartment*, *zip+4*, and *country*. In the data mapper, you need to identify these fields as missing. Again, you add padding fields at indexes 3, 7, and 8. See [Combine multiple source fields into one target field](#).

## 4.4. Combine multiple source fields into one target field

In a data mapping, you can combine multiple source fields into one compound target field. For example, you can map the **FirstName** and **LastName** fields to the **CustomerName** field.

### Prerequisite

For the target field, you must know what type of content is in each part of this compound field, the order and index of each part of the content, and the separator between parts, such as a space or comma. See [Example of missing or unwanted data when combining or separating fields](#).

### Procedure

1. In the **Target** panel, click the field into which you want to map more than one source field.
2. In the **Sources** panel, if there is a field that contains the fields that you want to map to the target field, then click that container field to map all contained fields to the target field.

To individually select each source field, click the first field that you want to combine into the target field. For each of the other fields that you want to combine into the target field, hover over that field, and press **CTRL-Mouse1** (**CMD-Mouse1** on MacOS).

The data mapper automatically changes the field action from **Map** to **Combine**.

When you are done you should see a line from each of the source fields to the target field.

3. In the **Mapping Details** panel, in the **Separator** field, accept or select the character that the data mapper inserts in the target field between the content from different source fields. The default is a space.
4. In the **Mapping Details** panel, under **Sources**, ensure that the source fields are in the same

order as the corresponding content in the compound target field.

If necessary, drag and drop source fields to achieve the same order. The data mapper automatically updates the index numbers to reflect the new order.

5. If you mapped a source field to each part of the compound target field, then skip to the next step.

If the target field expects data that is not available to be mapped, then in the **Mapping Details** panel, edit the index of each source field so that it is the same as the index of the corresponding data in the compound target field. The data mapper automatically adds padding fields as needed to indicate missing data.

If you accidentally create too many padding fields, click the trash icon on each extra padding field to delete it.

6. Optionally, preview the data mapping result:
  - a. In the upper right of the data mapper, click  and select **Show Mapping Preview** to display a text input field on each source field for the currently selected mapping and a read-only result field on the target field of the currently selected mapping.
  - b. In the source data input fields, enter text. Click outside the text box to display the mapping result in the read-only field on the target field.

If you reorder the source fields or add a transformation to the mapping then the result field on the target field reflects this. If the data mapper detects any errors, it displays informative messages at the top of the **Mapping Details** panel.

- c. Hide the preview fields by clicking  again and selecting **Show Mapping Preview**.

If you redisplay the preview fields, any data that you entered in them is still there and it remains there until you exit the data mapper.

7. To confirm that the mapping is correctly defined, in the upper right, click  to display the defined mappings. A mapping that combines the values of more than one source field into one target field looks like this:

## Mappings

 Sources	 Targets	 Type
/FirstName ⚡	/first_and_last_name	Combine
/LastName ⚡		(Space [ ]) .

You can also preview mapping results in this view. Click , select **Show Mapping Preview**, and enter text as described in the previous step. Preview fields appear for only the selected mapping. Click another mapping in the table to view preview fields for it.

## 4.5. Separate one source field into multiple target fields

In a data mapping, you can separate a compound source field into multiple target fields. For example, map the **Name** field to the **FirstName** and **LastName** fields.

### *Prerequisite*

For the source field, you must know what type of content is in each part of this compound field, the order and index of each part of the content, and the separator between parts, such as a space or comma. See [Example of missing or unwanted data when combining or separating fields](#).

### *Procedure*

1. In the **Sources** panel, click the field whose content you want to separate.
2. In the **Target** panel, click the first field that you want to separate the source field data into.
3. In the **Target** panel, for each additional target field that you want to contain some of the data from the source field, hover over the field and press **CTRL-Mouse1** (**CMD-Mouse1** on MacOS) to select it.

The data mapper automatically changes the field action to **Separate**.

When you are done selecting target fields, you should see lines from the source field to each of the target fields.

4. In the **Mapping Details** panel, in the **Separator** field, accept or select the character in the source field that indicates where to separate the source field values. The default is a space.
5. In the **Mapping Details** panel, under **Targets**, ensure that the target fields are in the same order as the corresponding content in the compound source field.

If necessary, drag and drop target fields to achieve the same order. The data mapper automatically updates the index numbers to reflect the new order.

6. If you mapped each part of the compound source field to a target field, then skip to the next step.

If the source field contains data that you do not need, then in the **Mapping Details** panel, edit the index of each target field so that it is the same as the index of the corresponding data in the compound source field. The data mapper automatically adds padding fields as needed to indicate unwanted data.

7. Optionally, preview the data mapping result:
  - a. In the upper right of the data mapper, click  and select **Show Mapping Preview** to display a text input field on the source field and read-only result fields on each target field.
  - b. In the source field's data input field, enter text. Be sure to enter the separator character between the parts of the field. Click outside the text box to display the mapping result in the read-only fields on the target fields.

If you reorder the target fields or add a transformation to a target field then the result fields

on the target fields reflect this. If the data mapper detects any errors, it displays informative messages at the top of the **Mapping Details** panel.

- c. Hide the preview fields by clicking  again and selecting **Show Mapping Preview**.

If you redisplay the preview fields, any data that you entered in them is still there and it remains there until you exit the data mapper.

8. To confirm that the mapping is correctly defined, click  to display defined mappings. A mapping that separates the value of a source field into multiple target fields looks like this:

## Mappings

 Sources	 Targets	 Type
/user/name	/FirstName ⚡ /LastName ⚡	Separate (Space [ ]) .

You can also preview mapping results in this view. Click , select **Show Mapping Preview**, and enter text as described in the previous step. Preview fields appear for only the selected mapping. Click another mapping in the table to view preview fields for it.

## 4.6. Transform source or target data

In the data mapper, after you define a mapping, you can transform any field in the mapping. Transforming a data field defines how you want to store the data. For example, you could specify the **Capitalize** transformation to ensure that the first letter of a data value is uppercase.

### *Procedure*

Map the fields. This can be a one-to-one mapping, a combination mapping, or a separation mapping.

1. **Select the transformation icon.**

In the **Mapping Details** panel, under **Sources** or under **Targets**, in the box for the field that you want to transform, click the arrow to the left of the trash can icon.

This displays a pull-down where you can select the transformation that you want the data mapper to perform. Note that the set of available transformations is type specific.

## 2. Select the transformation.

Click the transformation that you want to perform.

## 3. Specify arguments.

If the transformation requires any input parameters, specify them in the appropriate input fields.

## 4. Repeat.

To add another compound transformation, click the arrow to the left of the trash can icon again.

### Additional resource

#### [Descriptions of available transformations](#)

In addition to the list of fixed transformations, users may define their own custom field action transformations. These custom field actions are written in Java and are then imported into the AtlasMap data mapper. Once established in a panel the transformation will appear in the standard list of transformations. For example:

### Procedure

#### 1. Create a transformation.

This example custom transformation is applicable to `String` arguments. It takes the argument specified in the Source panel transformation and prints it out on the Target side. Implement the `AtlasFieldAction` class as follows:

```
package io.atlasmap.service.my;

import io.atlasmap.v2.*;
import io.atlasmap.api.AtlasFieldAction;
import io.atlasmap.spi.AtlasFieldActionInfo;

public class PaulsFieldActions implements AtlasFieldAction {

    @AtlasFieldActionInfo(name = "MyCustomFieldActionPaul", sourceType =
FieldType.STRING,
        targetType = FieldType.STRING, sourceCollectionType = CollectionType.NONE,
        targetCollectionType = CollectionType.NONE)
    public static String myCustomFieldAction(String input) {
        return "Paul's custom field action: " + input;
    }

}
```

## 2. Build your Java archive file.

The `io.atlasmap.v2`, `io.atlasmap.api` and `io.atlasmap.spi` target dependencies are most easily resolved through the use of a maven `pom.xml` file. Use the same version number as the AtlasMap standalone JAR that you previously downloaded.

## 3. Import your Java archive file.

Click the import icon at the top of the AtlasMap main tool bar.

Navigate to the JAR file containing your custom field action and select it.

#### 4. Enable your class

Select the plus icon (+) to enable the class within your field action JAR file.

A dialog appears "Establish your class in the Sources panel." In the **Class package name:** input field, enter the class package name of the Java class you have defined for your custom field action. In the `MyFieldAction.jar` example, the class package name is `io.atlasmap.service.my.PaulsFieldActions`.

## 5. Select your custom transformation.

Select the pull-down menu in the **Targets** window within the **Mapping Details** section. You will notice that your custom field action now appears as a selectable field action transformation. Select it.

## 6. Test your custom field action.

Select the  icon on the AtlasMap main tool bar. Check the checkbox for **Show Mapping Preview**.

In the Source panel there will exist an input field. Type a string into it (for example **test**). Now focus your cursor in the **Preview Results** field in the Target panel. You will see the same string.

## 4.7. Applying conditions to mappings

In some integrations, it is helpful to add conditional processing to a mapping. For example, suppose that you are mapping a source zip code field to a target zip code field. If the source zip code field is empty, you might want to fill the target field with **99999**. To do this, you would specify an expression that tests the zip code source field to determine if it is empty, and if it is empty, inserts **99999** into the zip code target field.

The data mapper supports expressions that are similar to a Microsoft Excel expressions, but does not support all Microsoft Excel expression syntax.

You can define zero or one condition for each mapping.

The following procedure gets you started with applying conditions to mappings. As you work with mappings and conditions, you can perform the required steps in the order that is most convenient for you.

### Prerequisites

- You are mapping fields in a the data mapper UI.
- You are familiar with Microsoft Excel expressions or you have the conditional expression that you want to apply to a mapping.

## Procedure

1. If data types are not already visible, display them by clicking  and then **Show Types**.

While this is not a requirement for specifying a condition, it is helpful to see the data types.

2. Create the mapping that you want to apply a condition to, or ensure that the currently selected mapping is the mapping that you want to apply a condition to. For example, consider this mapping:

3. In the upper right, click  to display the conditional expression input field.

In the expression field, the data mapper automatically displays the names of the source fields in the current mapping. For example:

In the expression input field, the order of the source fields is the order in which you selected them when you created the mapping. This is important because the default mapping behavior is that the data mapper concatenates the field values in this order to insert the result in the target field. In this example, to create this mapping, **lastName** was selected first and then **firstName** was selected.

4. Edit the expression input field to specify the conditional expression that you want the data mapper to apply to the mapping. Details about supported conditional expressions follow this procedure.

As you specify the expression, you can:

- Enter **@** and start to enter the name of a field. The data mapper displays a list of the fields that match what you entered. Select the field that you want to specify in the expression.
- Drag a field from the mapping canvas into the expression input field.

When you add a field name to the expression, the data mapper adds that field to the mapping. For example, consider this conditional expression:

During execution, if the data mapper determines that the **lastName** field is empty, it maps only the **firstName** field to the target **customerName** field. If the **lastName** field contains a value,

that is, it is not empty, the data mapper concatenates the values in the source `orderId` and `phone` fields, and inserts the result in the `customerName` field. (This example shows how the logic works, but it is probably not a useful example because when there is a value in the `lastName` field, you most likely want the data mapper to simply perform the mapping and not map some other value into the target.)

For this example, after you complete entering the expression, the data mapping is:

In the conditional expression, if you remove a field name that is in the mapping that the expression applies to, the data mapper removes that field from the mapping. In other words, every field name in the mapping must be in the conditional expression.

5. If mapping preview fields are not already visible, display them by clicking  and then **Show Mapping Preview**.
6. Enter sample data in the source preview input field(s) to ensure that the target field or target fields get(s) the correct value.
7. Optionally, apply transformations to one or more source or target fields that are in the mapping:
  - a. In the **Mapping Details** panel, find the field that you want to apply a transformation to.
  - b. Just below it, click **Add Transformation**.
  - c. Click the transformation that you want the data mapper to perform.
  - d. If needed, specify input parameters.

For example, in the same mapping presented in this procedure, in the **Mapping Details** panel, you could apply the `Uppercase` transformation to the `firstName` field. You can test this by entering data in the `firstName` field's preview input field.

8. Edit the conditional expression as needed to obtain the desired result.

#### *Supported functions in conditional expressions*

- `IEMPTY(source-field-name1 [+ source-field-name2])`

The result of the `IEMPTY()` function is a Boolean value. Specify at least one argument, which is the name of a source field in the mapping that you want to apply the condition to. When the specified source field is empty, the `IEMPTY()` function returns true.

Optionally, add the `+` (concatenation) operator with an additional field, for example:

```
IEMPTY(lastName + firstName)
```

This expression evaluates to true if both source fields, `lastName` and `firstName`, are empty.

Often, the `IEMPTY()` function is the first argument in an `IF()` function.

- `IF(boolean-expression, then, else)`

When `boolean-expression` evaluates to true, the data mapper returns `then`. When `boolean-expression` evaluates to false, the data mapper returns `else`. All three arguments are required.

The last argument can be null, which means that nothing is mapped when `boolean-expression` evaluates to false.

For example, consider the mapping that combines the `lastName` and `firstName` source fields in the target `customerName` field. You can specify this conditional expression:

```
IF (ISEMPTY(lastName), firstName, lastName + ',' + firstName )
```

During execution, the data mapper evaluates the `lastName` field.

- If the `lastName` field is empty, that is, `ISEMPTY(lastName)` returns true, the data mapper inserts only the `firstName` value into the target `customerName` field.
- If the `lastName` field contains a value, that is, `ISEMPTY(lastName)` returns false, the data mapper maps the `lastName` value, followed by a comma, followed by the `firstName` value into the target `customerName` field.

Now consider the behavior if the third argument in this expression is null:

```
IF (ISEMPTY(lastName), firstName, null )
```

During execution, the data mapper evaluates the `lastName` field.

- As in the previous example, if the `lastName` field is empty, that is, `ISEMPTY(lastName)` returns true, the data mapper inserts only the `firstName` value into the target `customerName` field.
- However, when the third argument is null, if the `lastName` field contains a value, that is, `ISEMPTY(lastName)` returns false, the data mapper does not map anything into the target `customerName` field.

Table 1. Supported operators in conditional expressions

Operator	Description
+	Add numeric values or concatenate string values.
-	Subtract a numeric value from another numeric value.
*	Multiply numeric values.
\	Divide numeric values.
&& And	Return true if both the left and right operands are true. Each operand must return a Boolean value.
 Or	Return true if the left operand is true, or if the right operand is true, or if both operands are true. Each operand must return a Boolean value.
!	Not
> Greater than	Return true if the left numeric operand is greater than the right numeric operand.
< Less than	Return true if the left numeric operand is less than the right numeric operand.
== Equal	Return true if the left operand and the right operand are the same.

## 4.8. View the mappings

While you are using the data mapper UI, you can view the mappings that are already defined. This lets you check whether the correct mappings are in place.

### Prerequisites

The data mapper canvas is visible.

### Procedure

1. In the upper right, click  to display a list of the defined mappings.
2. To dismiss the list of mappings and redisplay the source and target fields, click  again.

## 4.9. Descriptions of available transformations

TODO Generate this list automatically from annotation - <https://github.com/atlasmap/atlasmap/issues/173>

The following table describes the available transformations. The date and number types refer generically to any of the various forms of these concepts. That is, number includes, for example, *integer*, *long*, *double*. Date includes, for example, *date*, *Time*, *ZonedDateTime*.

Transformation	Input Type	Output Type	Parameter (* = required)	Description
<i>AbsoluteValue</i>	number	number	None	Return the absolute value of a number.
<i>AddDays</i>	date	date	<i>days</i>	Add days to a date. The default is 0 days.
<i>AddSeconds</i>	date	date	<i>seconds</i>	Add seconds to a date. The default is 0 seconds.
<i>Append</i>	string	string	string	Append a string to the end of a string. The default is to append nothing.
<i>Camelize</i>	string	string	None	Convert a phrase to a camelized string by removing whitespace, making the first word lowercase, and capitalizing the first letter of each subsequent word.

Transformation	Input Type	Output Type	Parameter (* = required)	Description
Capitalize	string	string	None	Capitalize the first character in a string.
Ceiling	number	number	None	Return the whole number ceiling of a number.
Contains	any	Boolean	value	Return true if a field contains the specified value.
ConvertAreaUnit	number	number	fromUnit* toUnit*	Convert a number that represents an area to another unit. For the fromUnit and toUnit parameters, select the appropriate unit from the <b>From Unit</b> and <b>To Unit</b> menus. The choices are: Square Foot, Square Meter, or Square Mile.
ConvertDistanceUnit	number	number	fromUnit* toUnit*	Convert a number that represents a distance to another unit. For the fromUnit and toUnit parameters, select the appropriate unit from the <b>From Unit</b> and <b>To Unit</b> menus. The choices are: Foot, Inch, Meter, Mile, or Yard.

Transformation	Input Type	Output Type	Parameter (* = required)	Description
ConvertMassUnit	number	number	fromUnit * toUnit *	Convert a number that represents mass to another unit. For the fromUnit and toUnit parameters, select the appropriate unit from the <b>From Unit</b> and <b>To Unit</b> menus. The choices are: <b>Kilogram</b> or <b>Pound</b> .
ConvertVolumeUnit	number	number	fromUnit * toUnit *	Convert a number that represents volume to another unit. For the fromUnit and toUnit parameters, select the appropriate unit from the <b>From Unit</b> and <b>To Unit</b> menus. The choices are: <b>Cubic Foot</b> , <b>Cubic Meter</b> , <b>Gallon US Fluid</b> , or <b>Liter</b> .
CurrentDate	None	date	Note	Return the current date.
CurrentDateTime	None	date	None	Return the current date and time.
CurrentTime	None	date	None	Return the current time.
DayOfWeek	date	number	None	Return the day of the week (1 through 7) that corresponds to the date.
DayOfYear	date	number	None	Return the day of the year (1 through 366) that corresponds to the date.

Transformation	Input Type	Output Type	Parameter (* = required)	Description
EndsWith	string	Boolean	string	Return true if a string ends with the specified string, including case.
Equals	any	Boolean	value	Return true if a field is equal to the specified value, including case.
FileExtension	string	string	None	From a string that represents a file name, return the file extension without the dot.
Floor	number	number	None	Return the whole number floor of a number.
Format	any	string	template *	In template, replace each placeholder (such as %s) with the value of the input field and return a string that contains the result. This is similar to mechanisms that are available in programming languages such as Java and C.
GenerateUUID	None	string	None	Create a string that represents a random UUID.
IndexOf	string	number	string	In a string, starting at 0, return the first index of the specified string. Return -1 if it is not found.
IsNull	any	Boolean	None	Return true if a field is null.

Transformation	Input Type	Output Type	Parameter (* = required)	Description
LastIndexOf	string	number	string	In a string, starting at 0, return the last index of the specified string. Return -1 if it is not found.
Length	any	number	None	Return the length of the field, or -1 if the field is null.
Lowercase	string	string	None	Convert a string to lowercase.
Normalize	string	string	None	Replace consecutive whitespace characters with a single space and trim leading and trailing whitespace from a string.
PadStringLeft	string	string	padCharacter * padCount *	Insert the character supplied in padCharacter at the beginning of a string. Do this the number of times specified in padCount.
PadStringRight	string	string	padCharacter * padCount *	Insert the character supplied in padCharacter at the end of a string. Do this the number of times specified in padCount.
Prepend	string	string	string	Prefix string to the beginning of a string. the default is to prepend nothing.

Transformation	Input Type	Output Type	Parameter (* = required)	Description
ReplaceAll	string	string	match * newString	In a string, replace all occurrences of the supplied matching string with the supplied newString. The default newString is an empty string.
ReplaceFirst	string	string	match * newString *	In a string, replace the first occurrence of the specified match string with the specified newString. The default newString is an empty string.
Round	number	number	None	Return the rounded whole number of a number.
SeparateByDash	string	string	None	Replace each occurrence of whitespace, colon (:), underscore (_), plus (+), and equals (=) with a hyphen (-).
SeparateByUnderscore	string	string	None	Replace each occurrence of whitespace, colon (:), hyphen (-), plus (+), and equals (=) with an underscore (_).
StartsWith	string	Boolean	string	Return true if a string starts with the specified string (including case).

Transformation	Input Type	Output Type	Parameter (* = required)	Description
Substring	string	string	startIndex * endIndex	Retrieve a segment of a string from the specified inclusive <b>startIndex</b> to the specified exclusive <b>endIndex</b> . Both indexes start at zero. <b>startIndex</b> is inclusive. <b>endIndex</b> is exclusive. The default value of <b>endIndex</b> is the length of the string.
SubstringAfter	string	string	startIndex * endIndex match *	Retrieve the segment of a string after the specified <b>match</b> string from the specified inclusive <b>startIndex</b> to the specified exclusive <b>endIndex</b> . Both indexes start at zero. The default value of <b>endIndex</b> is the length of the string after the supplied <b>match</b> string.
SubstringBefore	string	string	startIndex * endIndex match *	Retrieve a segment of a string before the supplied <b>match</b> string from the supplied inclusive <b>startIndex</b> to the supplied exclusive <b>endIndex</b> . Both indexes start at zero. The default value of <b>endIndex</b> is the length of the string before the supplied <b>match</b> string.

Transformation	Input Type	Output Type	Parameter (* = required)	Description
Trim	string	string	None	Trim leading and trailing whitespace from a string.
TrimLeft	string	string	None	Trim leading whitespace from a string.
TrimRight	string	string	None	Trim trailing whitespace from a string.
Uppercase	string	string	None	Convert a string to uppercase.

# Chapter 5. Export Files in UI

## 5.1. Export AtlasMap Data Mapper Catalog File

Once all required schema files and JARs have been imported and all mappings have been defined you can save your work using the **export** button. The export button captures all of your workspace into an ADM (**.adm**) catalog file. This file may be used with the **import** button to reinitialize AtlasMap to the state at which the export button was clicked. The export button can be found on the main toolbar:

Once it is clicked, an **Export mappings** dialog appears. A standard default name for the ADM file appears as a placeholder (**atlasmap-mapping.adm**). You may override that file name as desired.

Once you click the **OK** button the catalog file will be written with the specified name to the local **Downloads** directory.

# Chapter 6. Reset Files in UI

## 6.1. Reset the AtlasMap Data Mapper

Upon initial installation of AtlasMap the user is presented with a blank canvas. No mappings are possible until the user imports files into the Source and Target panels. Once imported, users may remove imported files using the trash can icon:

If a user wishes to remove **all** imported files as well as all mappings then select the  icon on the AtlasMap main tool bar and select **Reset All** from the pull down menu.

A challenge dialog will appear to verify that the user wants to remove all files.

Once the **Reset** button is clicked AtlasMap is reset and the user is presented with a fresh blank canvas.
